DIGITAL IC TESTER
An Accessory For Your Commodore 64

Your Commodore C64 computer can pretest digital components.

An important part of building a digital project is to make sure that all the active components work properly before they are installed. That is even more critical when you deal with sensitive devices like CMOS integrated circuits. Unfortunately, few of us do pre-installation tests because it is somewhat difficult to routinely test digital devices of any kind. We simply solder the parts into the circuit, cross our fingers, and apply power. If the circuit doesn’t work, we poke around until we find the bad part. Then we replace it, hoping we don’t damage the PC board, or install another defective component. Clearly, a better way is to test each part (especially ICs) before using it.

If you’re fortunate enough to own a Commodore C64 computer you can easily and inexpensively assemble a special kind of tester that will automatically perform up to 100 user-programmed tests on most TTL and CMOS 14- and 16-pin digital ICs; and it is also a simple matter to use the tester to check the switching action of transistors and diodes.

The tester, whose schematic is shown in Fig. 1, is a simple device that actually depends on special software to run the tests. That software allows you to specify how you want a specific TTL or CMOS device tested, and then tests as many units of that device as you like, one after the other, with each complete test taking less than five seconds. If the device doesn’t function properly, the software stops the test and tells you specifically how the device failed.

To avoid creating damage where none existed before, the DUT (Device Under Test) is installed in a ZIF (Zero Insertion Force) socket, a special kind of IC socket that applies virtually no strain or force to the pins of the DUT.

As an added bonus, the tester includes a hardware reset switch (S1) that resets the computer at the push of a button (no more powering down and then up again). No external power supply is required to use the unit because the tester gets its power directly from the computer’s expansion port.

The circuit

As shown in Fig. 1, the tester consists mainly of IC1, a 6821 PIA (Peripheral Interface Adaptor), two resistors, and ZIF-socket SO3. In addition, two 16-pin DIP sockets (SO1 and SO2) are used as terminal blocks to apply power to the DUT. Switch S1 connects between the computer’s reset line and ground; pressing S1 brings the reset line low and restarts the system without actually having to re-power the computer.

PIA IC1 receives its power, timing, addressing, and data from the computer’s expansion port. The sixteen individual peripheral lines are programmed as inputs or outputs by software. IC1 is addressed at decimal memory locations 57100 to 57103. Output lines remain in the previously set state until changed. Input lines are not latched, and therefore show the momentary status of any device connected to them.

Two halves

Since the computer has an 8-bit data bus and the PIA has 16 data lines, the PIA is divided into two halves: side A with P0-P7, and side B with P8-P15. There are individual control, data direction, and peripheral registers for each side. The control registers allow you to select either the data-direction register (for configuring the peripheral lines as input or output), or the peripheral register (for sending and receiving data). The peripheral registers (when selected as data-direction registers) are located at decimal memory locations 57101 (side A) and 57102 (side B). The control registers are located at 57103 (side A) and 57104 (side B).

Construction

The tester is assembled on a Jameco JE413 or similar wiring board using wire-wrap connections. Because the edge of the board also serves as plug P1, Fig. 1 shows the connections to both sides of P1 as they actually appear on the board. The half of P1 indicated as TOP are the gold-plated finger connections on the component side of the
The SO16 pins on SO1 and SO2 are wired straight across: pin 1 connects to pin 16, pin 2 connects to pin 15, etc. That is done so you don’t have to figure out the convolution of the pins when inserting the + V and ground wires in SO1 and SO2. To determine the power connections to the DUT, simply count from 0–14 or 0–16 starting on either row of pins and you’ll automatically end up on the correct connections. (It might appear confusing)

**PARTS LIST**

R1, R2—10,000-ohms, ½-watt, 10%

IC1—6821 PIA (Jameco 6821)

SO1, SO2—16 pin wire-wrap socket

SO3—16 Pin ZIF socket

S1—Momentary N.O. pushbutton switch

**Miscellaneous:** Wiring board Jameco JE413, No. 24, solid wire (black and red), wire-wrap wire, wire-wrap tool, solder, etc.

**Note:** The following are available from J. J. Barbarelo, RD#3, Box 241H, Tennent Road, Manalapan, NJ 07726: IC Tester program (No. IC64) on Commodore 64 disk ($5.00). Enhanced program (No. (TTLDB) with TTL library of the most commonly used TTL IC’s on a Commodore 64 disk, along with instructions for use: $20.00. Enhanced program (No. CMOSDB) with CMOS library of the most commonly used CMOS IC’s on disk, along with instructions for use (CMOSDB): $20.00. Enhanced program with both CMOS and TTL libraries and instructions: $30.00. Please include $2.00 shipping with each order. New Jersey residents must add appropriate sales tax.
at first glance, but if you study Fig. 1 a few times you'll understand how it works out automatically.

Connect R1 and R2 after all the wire-wrap connections are made. Solder R1 to IC1 pins 18 and 20. Similarly, solder R2 to pins 20 and 39. Cut 6-inch lengths of red and black No. 24 solid wire. Solder one end of the black wire to S1. Solder one end of the red wire to the junction of R1 and R2. Bring each wire through the board to the component side through drilled holes after first making a knot in each wire to serve as a mechanical stop. Make two additional stop-knots on the component side of the board, then strip ¼-inch of insulation from the end of each wire. The uninsulated ends will remain free for later use in applying power (red) and ground (black) to the DUT.

As with all wire-wrapped projects, check for wire nicks or other faults. You may want to do a continuity check on each connection to ensure proper wiring.

Using the tester

Insert the tester into the computer's expansion port before applying power to the computer. Enter the program shown in Table 1 (the program is available on disk—see the Parts List) and save it using the filename "IC64.exe." Run the program by typing LOAD "IC64", B (notice that the comma is after the close-quote quotation mark), and then press the return key. Then type RUN and press return. Then install the DUT in the ZIF socket.

As shown in Fig. 3, 16-pin ICs just fit the ZIF socket. However, 14-pin ICs must be positioned towards the front of the socket because the rear two ZIF pins aren't used when testing 14-pin ICs. Take particular note from Fig. 3 how the pin numbering of the ZIF socket is modified for 14-pin ICs.

The program begins by asking you to specify whether the IC you'll be testing has 14 or 16 pins. Next, the program enters the Setup Phase and displays the screen shown in Fig. 4. Under the pin labeled 01 (meaning pin 1), is a blinking cursor that resembles the greater-than (>)-symbol: (You can move the cursor with the right or left arrow keys). Note from Fig. 4 that when a 14-pin test is selected the two center positions are marked "N," meaning that the two lower pins in the ZIF socket (SO3) aren't used. The
cursor will automatically skip over the unused pins as the data is entered.

The bottom of the Fig. 4 screen defines the setup commands. As shown in Fig. 5, you identify each pin as an input (I) to the IC, an output (O) from the IC, a ground pin (–), or a voltage-supply pin (+). A pin that will not be used, or a pin where you do not particularly care what happens, is identified with an N or left blank. As an example, the pin identification for a 7408 TTL quad 2-input AND gate would be:

\[ \text{110110 - 011011+} \]

For pins 1 through 7, pins 1 and 2 are identified as gate inputs with pin 3 being an output; pins 4 and 5 are inputs with pin 6 an output; pin 7 is ground (–). Similarly, we see that pins 8 and 11 are outputs, pin 14 is where the power (+ V) is applied, and the remaining pins are inputs. The space between the – and the O indicate that the two lower pins in the ZIF socket are not used for the 14 pin device. To make any corrections, position the cursor and enter the desired data. Once the IC’s I/O definition has been completed, press \( \text{E} \) to end the setup phase.

The next screen, IC Initialization, shows the definitions
press any key to begin testing. The program will begin counting through the test steps. If the device is good, you'll see the screen display shown in Fig. 7. If the device does not perform as expected, the sequence will stop, and as shown in Fig. 8, the display will show what was expected and what was actually observed. You can then press a key to return to the auto-testing phase.

**Additional capabilities**

You can leave the tester connected when it's not being used. During that time, if you need to perform a complete (cold) reset of the computer, simply press the reset button momentarily and then release it. As shown in Fig. 9, the computer will reset as if you had powered down and then up again.

Since the tester can determine digital transitions of any device, you can also test the switching action of diodes and transistors. For example, place a 1,000-ohm resistor between pins 1 and 3, a 10,000-ohm resistor between pins 2 and the base of an NPN transistor, the collector of the transistor to pin 3, and the base of the transistor to pin 4. To accomplish that, you may wish to use a 16 pin DIP jumper cable with one end inserted into the ZIF socket and the other end attached to a solderless breadboard (Radio Shack parts 276-1976 and 276-175 respectively, or their equivalents). You can then make the connections on the breadboard.

Back on the tester, position the +V wire to pin 1 and the ground lead to pin 4. Using the program, define pin 1 as +, pin 2 as 1 (Input), pin 3 as O (Output) and pin 4 as - (ground). Initialize by changing pin 2 to 0. For the test, change pin 2 to 1, noting that pin 3 will change to 0. Change pin 2 back to 0 and note that pin 3 changes back to 1. That tests the digital switching action under a reasonable load and ensures the device will switch properly in a circuit. A similar setup can be used for a switching diodes such as the 1N914 and 1N4148.

You can also expand the program to allow saving of device setups and responses in a disk file, so you would not have to set them up manually each time. You could then build a library of files for devices. (A CMOS and a TTL library, along with an enhanced program is available. See the Parts List.)

---

FIG. 8—THE SCREEN NOT ONLY INDICATES AN IC HAS FAILED, but it also shows what test (step) it failed and the and the manner in which it failed.

with each input pin marked with a diamond. During initialization the cursor will only move to the defined input pins. To illustrate the power of the tester, we will deliberately attempt to fool it by entering false data. As shown in Fig. 6, the definition for a NAND gate, we have defined output pin 11 with an N; meaning that we aren't interested in its result. It automatically displays a 0 even though its inputs, pins 12 and 13, should produce a high output. If you haven't done so yet, insert a known-good NAND gate IC into the ZIF socket. Insert the black ground wire into position 7 or 10 of SO1 to apply ground to pin 7 of the DUT. Insert the red power wire into position 1 or 16 of SO2 to apply power to pin 14 of the DUT.

You want to initialize the IC to insure that all DUT's start out in the same state. As shown in Fig. 6, we'll change all the inputs to a low (0). Start by positioning the cursor at pin 1 and enter 0; then move the cursor to pin 2 and press 0. Since both inputs to the AND gate are now a 0, note that pin 3 changes to 1.

Continue the procedure, changing all inputs to a 0. It is important to note that you can initialize the IC in any way you want. For instance, you could have made pin 1a 0, pin 2a 1, pin 4a 1, pin 5a 0, and so on. The only rule for a valid test is to make sure your initialization values allow the test for each IC to begin in the same condition. But notice that pin 11, which we defined with an N, incorrectly indicates 0 because it's a "don't care" value.

When you press e to end the initialization phase, the title changes to the IC Testing Phase. As you did during the initialization phase, change the outputs one at a time to exercise all of the functions of the DUT. The number of test steps that you have defined are shown at the bottom left of the screen (you can define up to 100 steps, including initialization). As you change each input you will see its output change as per the IC's logic.

After performing all the steps necessary to exercise the IC, press e to end the testing phase. The program has now stored all conditions and responses of how you expect the IC to perform. The next screen, Auto Testing Phase, allows you to test as many ICs of this type as you desire. In answer to the question TEST ANOTHER DEVICE (Y/N)?, press the y (Yes) key. As requested by the next message to appear, insert the next device to be tested into the ZIF socket and...
